

Trauma Bandage Users Manual

The trauma bandage is an effective and simple pressure bandage used to treat bleeding wounds that are not life-threatening. The trauma bandage has a non-adherent large sterile pad surface that helps to cover the injury. The pad is connected to a latex-free elastic material and allows for removing the bandage without having to reopen the wound.

Here is a detailed guide on how to properly use a traumatic bandage.

- Open the packaging of the bandage by ripping one off the top corners.
- Separate the bandage from the inner wrap.
- Spread the bandage open. In spreading the bandage, the hands do not touch the sterile part. Put one hand on the first end, while the other hand is used to open the bandage's wrap roll.
- Place the bandage on the wound so that the pressure applicator will be positioned and the side of the wound.
- Wrap the bandage around the wound site once, then pass it through the pressure applicator, and then wrap it in the opposite direction. Make sure it is tight as you wrap.
- When done wrapping, place the closure bar ends into two or more folds of the bandage to hold it in place.
